2 GENERAL CHEMISTRY TRANSLATED: FINDING THE ELECTRONS

ASSESSMENTS

A2.1

a. Answer:
C:$1s^2 2s^2 2p^2$

b. Answer:
N:$1s^2 2s^2 2p^3$

c. Answer:
O: $1s^2 2s^2 2p^4$

d. Answer:
F: $1s^2 2s^2 2p^5$

TBEXAM.COM

e. Answer:
H: $1s^1$

A2.2

Answer:

They have the same number of valence shell electrons.

Fully Worked Solution:

Elements in the same group react similarly because they have the same number of valence shell electrons. They require the same number of bonds/electrons to complete their valence shell and attain a noble-gas configuration.

A2.3

Answer:

Na Mg Si C N O F

Least electronegative Most electronegative

Fully Worked Solution:

Sodium's electronegativity is 0.9, magnesium's electronegativity is 1.2, silicon's electronegativity is 1.8, carbon's electronegativity is 2.5, nitrogen's electronegativity is 3.0, oxygen's electronegativity is 3.5, and fluorine's electronegativity is 4.0.

TBEXAM.COM - THE WORLD'S LARGEST TEST BANK AND SOLUTIONS DATABASE WITH UNBEATABLE RATES
Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

A2.4

a. Answer:
C: four valence shell electrons, can form four bonds

b. Answer:
N: five valence shell electrons, can form three bonds

c. Answer:
O: six valence shell electrons, can form two bonds

d. Answer:
F: seven valence shell electrons, can form one bond

e. Answer:
H: one valence shell electron, can form one bond

A2.5

Answer:

Argon has eight valence shell electrons and a filled outer shell. It does not need to form bonds to fill an octet.

A2.6

Answer:

The ball always rolls downhill.
Negatives attack positives.

TBEXAM.COM

A2.7

Answer:

79.903 amu

Fully Worked Solution:

$$\begin{aligned} &(78.918\ \text{amu} * 0.507) \\ &+ (80.916\ \text{amu} * 0.493) \\ &= \ 79.903\ \text{amu} \end{aligned}$$

A2.8

Answer:

75.76% ^{35}Cl, 24.24% ^{37}Cl

Fully Worked Solution:

$$(34.969\ \text{amu} * x) + (36.966\ \text{amu} * y) = 35.453\ \text{amu}$$

$$x + y = 1 \quad \therefore \quad y = 1 - x$$

$$(34.969\ \text{amu} * x) + (36.966\ \text{amu} * (1 - x)) = 35.453\ \text{amu}$$

$$34.969\ \text{amu}(x) + 36.966\ \text{amu} - 36.966\ \text{amu}(x) = 35.453\ \text{amu}$$

$$36.966\ \text{amu} - 35.453\ \text{amu} = 36.966\ \text{amu}(x) - 34.969\ \text{amu}(x)$$

$$1.513\ \text{amu} = 1.997\ \text{amu}(x)$$

$$x = 0.7576$$

$$y = 1 - 0.7576 = 0.2424$$

$\therefore$ 75.76% ^{35}Cl, 24.24% ^{37}Cl

Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

A2.9

Answer:

Electrons will be added to the 5p orbital before the 4f orbital. The 5p orbital is lower in energy than the 4f orbital; thus the 5p orbital will be filled first.

A2.10

a. Answer:

Fully Worked Solution:

Electrons in the 2p orbital are being paired before each orbital is occupied. Move one electron to the second 2p orbital.

b. Answer:

Hund's rule is not being followed.

Fully Worked Solution:

Hund's rule is not being followed. When two or more orbitals are degenerate (equal in energy), one electron is placed in each orbital with parallel spins before pairing electrons.

A2.11

Answer:

The 4s orbital is lower in energy than the 3d orbital.

Fully Worked Solution:

TBEXAM.COM

The 4s orbital is filled before the 3d orbital; thus, the 4s orbital must be lower in energy than the 3d orbital.

A2.12

Answer:

The 3s electrons will be more reactive than the 2s. The 3s electrons are higher in energy than the 2s electrons.

Fully Worked Solution:

The 3s electrons are further from the nucleus than the 2s. They are held less strongly and are higher in energy than the 2s orbital; thus, the 3s electrons should be more reactive.

A2.13

a. Answer:

Si

Fully Worked Solution:

The 3p shell is larger than the 2p shell.

b. Answer:

O

Fully Worked Solution:

The extra electron in the 2p shell of fluorine contracts the orbital and decreases the atomic radius.

TBEXAM.COM – THE WORLD'S LARGEST TEST BANK AND SOLUTIONS DATABASE WITH UNBEATABLE RATES
Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

c. Answer:
Br
Fully Worked Solution:
The 4p shell is larger than the 3p shell.

d. Answer:
S
Fully Worked Solution:
Even though sulfur has more electrons in its valence shell than nitrogen, decreasing the atomic radius compared to phosphorus, sulfur is in the third row and the 3p orbitals are larger than the 2p orbitals. Sulfur is larger than nitrogen.

A2.14

a. Answer:
Beryllium loses two electrons to achieve the noble-gas configuration of helium.
Fully Worked Solution:
Beryllium's electron configuration is $1s^2 2s^2$. If it loses two electrons, the electron configuration becomes $1s^2$, the electron configuration of the noble gas helium.

b. Answer:
Aluminum loses three electrons to achieve the noble-gas configuration of neon.
Fully Worked Solution:
Aluminum's electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^1$. If it loses three electrons, the electron configuration becomes $1s^2 2s^2 2p^6$, the electron configuration of the noble gas neon.

TBEXAM.COM

c. Answer:
Magnesium loses two electrons to achieve the noble-gas configuration of neon.
Fully Worked Solution:
Magnesium's electron configuration is $1s^2 2s^2 2p^6 3s^2$. If it loses two electrons, the electron configuration becomes $1s^2 2s^2 2p^6$, the electron configuration of the noble gas neon.

d. Answer:
Potassium loses one electron to achieve the noble-gas configuration of argon.
Fully Worked Solution:
Potassium's electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$. If it loses one electron, the electron configuration becomes $1s^2 2s^2 2p^6 3s^2 3p^6$, the electron configuration of the noble gas argon.

A2.15

a. Answer:
Oxygen gains two electrons to achieve the noble-gas configuration of neon.
Fully Worked Solution:
Oxygen's electron configuration is $1s^2 2s^2 2p^4$. If it gains two electrons, the electron configuration becomes $1s^2 2s^2 2p^6$, the electron configuration of the noble gas neon.

Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

b. Answer:
Iodine gains one electron to achieve the noble-gas configuration of xenon.
Fully Worked Solution:
Iodine's electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^5$. If it gains one electron, the electron configuration becomes $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^6$, the electron configuration of the noble gas xenon.

c. Answer:
Phosphorus gains three electrons to achieve the noble-gas configuration of argon.
Fully Worked Solution:
Phosphorus's electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^3$. If it gains three electrons, the electron configuration becomes $1s^2 2s^2 2p^6 3s^2 3p^6$, the electron configuration of the noble gas argon.

d. Answer:
Chlorine gains one electron to achieve the noble-gas configuration of argon.
Fully Worked Solution:
Chlorine's electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^5$. If it gains one electron, the electron configuration becomes $1s^2 2s^2 2p^6 3s^2 3p^6$, the electron configuration of the noble gas argon.

A2.16

a. Answer:
+1
Fully Worked Solution:
TBEXAM.COM
Lithium's electron configuration is $1s^2 2s^1$. If it loses one electron, the electron configuration becomes $1s^2$, the electron configuration of the noble gas helium.

b. Answer:
+3
Fully Worked Solution:
Aluminum's electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^1$. If it loses three electrons, the electron configuration becomes $1s^2 2s^2 2p^6$, the electron configuration of the noble gas neon.

c. Answer:
+1
Fully Worked Solution:
Potassium's electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$. If it loses one electron, the electron configuration becomes $1s^2 2s^2 2p^6 3s^2 3p^6$, the electron configuration of the noble gas argon.

d. Answer:
+2
Fully Worked Solution:
Beryllium's electron configuration is $1s^2 2s^2$. If it loses two electrons, the electron configuration becomes $1s^2$, the electron configuration of the noble gas helium.

TBEXAM.COM – THE WORLD'S LARGEST TEST BANK AND SOLUTIONS DATABASE WITH UNBEATABLE RATES
Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

A2.20

a. Answer:
Li is more electronegative than K.

b. Answer:
O is more electronegative than N.

c. Answer:
O is more electronegative than P.

d. Answer:
B is more electronegative than Si. (We need to look up the Pauling electronegativity values for B versus Si.) Si is down and to the right of B. Electronegativity increases to the right but decreases down, so relative electronegativity cannot be easily estimated. Based on the actual electronegativity values, B (2.0) is more electronegative than Si (1.8).

A2.21

Answer:
Elements in higher groups have fewer filled electron shells between the nucleus and the valence shell.
Fully Worked Solution:
Atoms lower in a group have several filled electron shells between the nucleus and the valence electrons. These inner electrons "shield" the nucleus (and its positive charge) from the valence electrons. This shielding effect causes elements lower in a group to have less affinity for an electron, and thus a lower electronegativity.

TBEXAM.COM

A2.22

Answer:
With a smaller radius, valence electrons "feel" the pull of the nucleus more.
Fully Worked Solution:
A smaller atomic radius means that the valence electrons "feel" the pull of the positively charged nucleus more. This causes the atoms to have a greater affinity for a new electron, and thus a higher electronegativity.

A2.23

Answer:
Larger atoms are less electronegative.
Fully Worked Solution:
A larger atomic radius means that the valence electrons "feel" the pull of the positively charged nucleus less. This causes the atoms to have less affinity for a new electron, and thus a lower electronegativity.

A2.24

a. Answer:
NaCl is ionic.
Fully Worked Solution:
Na = 0.9, Cl = 3.0 ΔEN = 2.1

Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

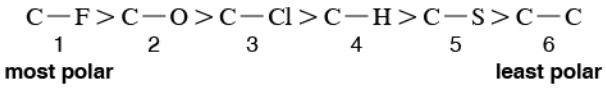

b. Answer:
C–H is covalent.
Fully Worked Solution:
C = 2.5, H = 2.1 ΔEN = 0.4

c. Answer:
O–O is covalent.
Fully Worked Solution:
O = 3.5 ΔEN = 0.0

d. Answer:
C–Cl is polar covalent.
Fully Worked Solution:
C = 2.5, Cl = 3.0 ΔEN = 0.5

A2.25

Answer:

Fully Worked Solution:
C = 2.5, F = 4.0, O = 3.5, Cl = 3.0, S = 2.5, H = 2.1
ΔC–F = 1.5, ΔC–O = 1.0, ΔC–Cl = 0.5, ΔC–H = 0.4, ΔC–S = 0.0, ΔC–C = 0.0

A2.26

a. Answer:

TBEXAM.COM

Fully Worked Solution:
Both atoms have the same electronegativity. The bond is nonpolar with no δ+ or δ–.

b. Answer:

Fully Worked Solution:
Oxygen is more electronegative and has the δ– charge.

c. Answer:

Fully Worked Solution:
Carbon is more electronegative and has the δ– charge.

d. Answer:

Fully Worked Solution:
Fluorine is more electronegative and has the δ– charge.

TBEXAM.COM

b. Answer:
0
Fully Worked Solution:
Al wants three electrons in the valence shell.
Al owns half of the six bonding electrons = 3.
3 − 3 = 0

c. Answer:
−1
Fully Worked Solution:
I wants seven electrons in the valence shell.
I owns eight lone pair electrons.
7 − 8 = −1

d. Answer:
+1
Fully Worked Solution:
N wants five electrons in the valence shell.
N owns half of eight bonding electrons = 4.
5 − 4 = 1

e. Answer:
0
Fully Worked Solution:
N wants five electrons in the valence shell.
N owns two lone pair electrons and half of six bonding electrons = 5.
5 − 5 = 0

TBEXAM.COM

f. Answer:
1
Fully Worked Solution:
O wants six electrons in the valence shell.
O owns six lone pair electrons and half of two bonding electrons = 7.
6 − 7 = −1

A2.29

a. Answer:

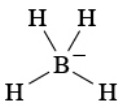

H: 1 − 1/2(2) = 0
O: 6 − 6 − 1/2(2) = −1

b. Answer:

H: 1 − 0 = +1

c. Answer:

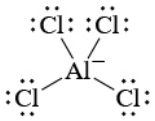

H: 1 − 1/2(2) = 0
B: 3 − 1/2(8) = −1

O: $6 - 2 - 1/2(6) = +1$

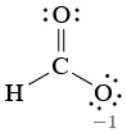

f. Answer:

H: $1 - 1/2(2) = 0$
N: $5 - 1/2(8) = +1$

A2.30

a. Answer:

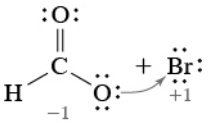

O: $6 - 6 - 1/2(2) = -1$

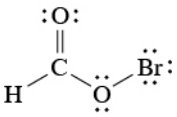

Br: $7 - 6 = +1$

TBEXAM.COM

b. Answer:

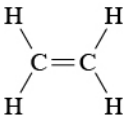

c. Answer:

A2.31

Answer:

Fully Worked Solution:

Two C + 4 = 12 valence electrons. The σ-bonds can only account for ten electrons. Putting the last two electrons as a lone pair on one carbon would give it a formal −1 charge, and the other carbon a formal +1 charge. However, sharing the final two electrons as a pi-bond between the two carbons makes all atoms neutral with a full octet.

TBEXAM.COM

TBEXAM.COM

A2.54

Answer:

Carboxylate: sp^2, alkoxide: sp^3, carboxylate more stable

Fully Worked Solution:

The carboxylate is resonance stabilized. The electrons are spread out over a larger volume; this makes the molecule more stable.

TBEXAM.COM - THE WORLD'S LARGEST TEST BANK AND SOLUTIONS DATABASE WITH UNBEATABLE RATES

Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

TBEXAM.COM

P2.78

Answer:

CO_2 is linear, SO_2 is trigonal planar.

Fully Worked Solution:

Carbon dioxide is a linear molecule, and the polar bonds are 180° opposed. The polar bonds cancel out, resulting in no net dipole.

Sulfur dioxide is a trigonal planar molecule, and the polar bonds are ~120° from each other. The dipoles corresponding to the two polar bonds do not cancel out in this case, so their combination results in a net dipole on sulfur dioxide.

P2.79

Answer:

Ethane only contains σ-bonds, which can freely rotate. Ethene contains a π-bond, which cannot freely rotate.

Fully Worked Solution:

The carbon atoms in ethane are connected through a σ-bond. The coaxial overlap of the orbitals means the bond can rotate and the orbitals are still fully overlapped.

The carbon atoms in ethene are connected through a σ- and a π-bond. The off-axial overlap of the p orbitals comprising the π-bond means that as the π-bond rotates, the p orbitals no longer overlap. To rotate about the π-bond in ethene would require breaking the π-bond, necessitating a high amount of energy.

P2.80

Answer:

The carbon atoms in ethane are sp^3 hybridized, while the carbon atoms in ethene are sp^2 hybridized.

TBEXAM.COM

Fully Worked Solution:

The carbon atoms in ethene are sp^2 hybridized. An sp^2-hybridized atom is more electronegative than an sp^3-hybridized atom. The electrons are held more tightly to the nucleus, and the sigma-bonds are shorter as a result.

P2.81

Answer:

All carbon atoms in the allyl cation are sp^2 hybridized, and the allyl cation can engage in resonance, making all bond lengths equal.

Fully Worked Solution:

The carbon atoms in the allyl cation are all sp^2 hybridized. An sp^2-hybridized atom is more electronegative than an sp^3-hybridized atom. The electrons are held more tightly to the nucleus, and the sigma-bonds are shorter as a result.

Additionally for the allyl cation, the molecule is resonance stabilized. The true structure of the resonance hybrid has a partial double bond between all carbon atoms. The partial double-bond character shortens the bond length.

P2.82

Answer:

The electrons would go into the empty, unhybridized p orbital on the carbon atom.

P2.83

Answer:

The oxygen has a complete octet and all orbitals are full. There is nowhere for a lone pair of electrons to add.

Organic Chemistry 1st edition Mullins Solutions Manual

TBEXAM.COM

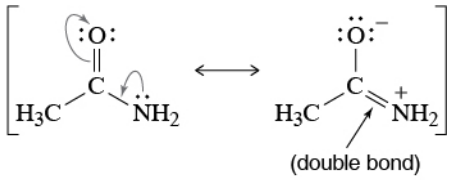

TBEXAM.COM

P2.84

Answer:

The lone pair of electrons on the nitrogen atom in the amide can be stabilized by resonance. The resonance stabilization makes the C–N bond of the amide a partial double bond. The significant double-bond character of the C–N bond in the amide makes the bond stronger than the nonresonance-stabilized C–N s-bond in the amine. As a consequence of the double-bond character, rotation about the C–N bond in the amide is considerably restricted.

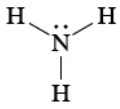

Fully Worked Solution:

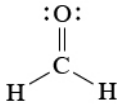

P2.85

a. Answer:

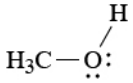

b. Answer:

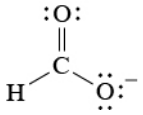

TBEXAM.COM

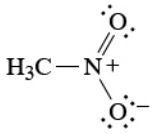

c. Answer:

d. Answer:

e. Answer:

P2.86

Answer:

The CH_3^- anion has a lone pair of electrons on carbon that can be donated to an electron acceptor (a Lewis acid) to form a new bond.
